

Summer heat protection

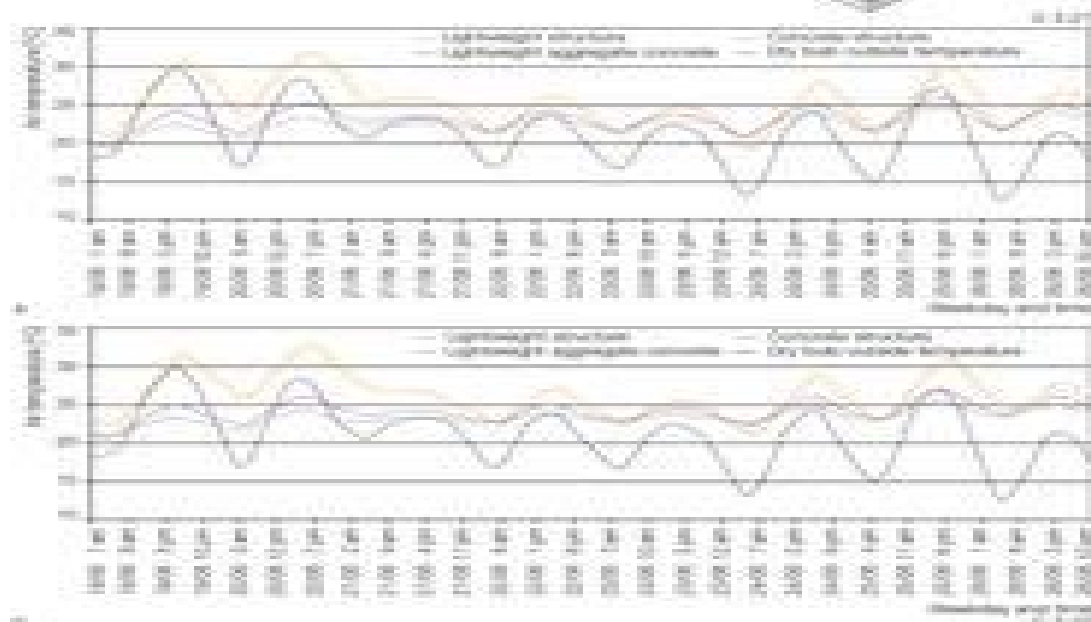

The construction of building envelopes with U-values of less than 0.2 W/m²K has significantly reduced energy exchange through thermal conductivity. Heat transfer between the inside and outside still takes place through radiation and convection (ventilation). During the summer, the thermal gains through solar radiation and the operation of electrical equipment and appliances are so high that they exceed the night time losses through thermal conductivity and the (negligible) radiation losses. Office buildings, with a high level of daytime occupancy combined with the heat from illumination and electrical equipment, are especially affected. Additionally, included

in non-residential buildings often feature a high proportion of glazing to provide daylight for the working areas. A simplified calculation of the summer heat protection (according to DIN 4108-5) can be made using some characteristic values. This takes account of the climate region, the relationship between the surface area of windows and the surface area of the relevant rooms as well as the quality of the windows.

Alternatively, the internal temperature of the individual rooms or zones of a building can be determined using thermal building simulations with temporally variable (dynamic) system boundary conditions by modelling the specific physical and technical parameters of a building

- Fig. 10.20: Model employed to simulate the internal temperature
- Fig. 10.21: Monthly variation in the operative room zone (average) at intermediate (21 June) without air exchange rate of 1.0 h⁻¹
 - a. with lightproof ventilation at 0.1 m³/h
 - b. without lightproof ventilation
- Fig. 10.22: Total system efficiency (depending on the use of the building and the actual energy demand for heating) is related to the surface area of the building
 - a. Low temperature (near 20 °C)
 - b. Conventional (near - combined with some thermal or fuel costs)
 - c. Heat pump system

and their generating energy flows over a given time period. The boundary surfaces of the outdoor example (Fig. 10.21b) are thermally insulated externally to Passive House standards, so the heat capacity of the building components can be used as a buffer. Wall and roof construction have the same low specific thickness mass (ca. 13.5 kg/m² of the total wall area) and are arranged equally on all four faces. Thermal transfer occurs through the surface of the outer envelope (system boundary) in the form of thermal conductivity, radiation and convection (ventilation). Other heat sources or sinks (heating, building equipment technology or similar) are not present. The daytime air exchange rate is $n = 0.5 \text{ h}^{-1}$ and can be increased to $n = 5.0 \text{ h}^{-1}$ during the night. Heating or cooling systems are not active during the simulation (25).

Fig. 10.22 shows the changes in the exterior and interior (operative) temperatures over the simulation period. It is clear that the exterior temperature shows periodic fluctuations. At the same time, variations over several days (heating and cooling) are identifiable. In principle, the interior temperature follows the course of the exterior temperature. However, the interaction between the course of the operative temperature and the effective heat storage capacity of the building structure is evident. With a lower heat storage capacity, the operative temperature shows pronounced fluctuations and follows the movement of the exterior temperature closely. With no heat storage mass, the building heats up markedly during the daytime; the peak temperatures become so high it is no longer comfortable and consequently the space has to be air-conditioned.

With greater effective heat storage capacity, the amplitude of the operative temperature compared to the exterior temperature is reduced considerably, and the room temperature fluctuates in a narrower range, which is well perceived as comfortable. Under these circumstances, cooling or air conditioning is not required. These results lead to the general conclusion that, given Germany's climate, the insulation of air-conditioning is not necessary if heat input can be restricted through the use of effective winter protection measures – in (1. external window glazing), and building components with effective heat storage capacity to store incoming heat. The temperature of the thermal store at the start of the sun's radiation should be as low as possible so that – proportional to the temperature difference – heat transfer is maximised and the temperature of the component after storing incoming thermal energy does not exceed approx. 20 °C. This storage requires the removal of the heat gained in building components during the day through convection to the outside (ventilation) in the cooler night hours, even in the medium-term months. This leads not only to a reduction in a building's primary energy consumption, but also reduces the investment and operating costs for equipment and systems.
