

When these parts are assembled by a press fit onto the shaft, the rotor assembly is completed. The rotor is supported by prelubricated bearings at each end of the shaft, a ball bearing in the drive end frame and a roller bearing in the opposite end frame.

Two slip rings upon which the brushes ride, are mounted on one end of the rotor shaft and are attached to the leads from the field coil. When the ignition switch is first closed, current from the battery passes through one brush, through the slip ring upon which the brush rides, and then through the field coil. After leaving the field coil, current flow continues through the other slip ring and brush before returning to the battery through the ground return path. This flow of electrical energy through the field winding is called *field current*.

When battery current flows through the field coil a magnetic field is formed with a North magnetic pole at each pole of one rotor segment and a South magnetic pole at each pole of the other segment. As the rotor turns, a spinning magnetic field is produced.

15

16

Let's look at a rotor and the most basic stator, which is a single loop of wire. As the magnetic field from the spinning rotor cuts across this wire, an electrical pressure or voltage is produced in the loop. The faster the rotor turns, the greater will be the voltage. Increasing the number of loops in the stator winding also increases the voltage.

The stator assembly is made up of a laminated iron frame and three stator or output windings which are wound into slots of the frame. The stator assembly is sandwiched between the two stationary end frames of the DELCOTRON generator.
