

## Lesson 6: Meiosis

Offspring produced by sexual reproduction are genetic clones of their parents, whereas offspring produced by asexual reproduction inherit genetic information from two parents. Each parent contributes a copy of half of its genetic information. This process of combining genetic information from two individuals results in offspring that differ genetically from their parents and from each other. In order for sexual reproduction to take place, gametes (or sex cells) must be produced such that they contain half the number of chromosomes (haploid -  $n$ ) as a somatic cell (diploid cell -  $2n$ ). If all organisms started from a fertilised, diploid cell, how is it that we have gametes, such as sperm and eggs that are haploid?

**Meiosis:** Meiosis is a two-stage cell division in which the resulting daughter cells have half the number of chromosomes as the parent cell. In every somatic cell, there are two copies of each chromosome, each from a parent. Homologous chromosomes are matching pairs of chromosomes, similar in size and carrying information for the same genes.

Figure 6.1 In meiosis, a single-celled eukaryotic parent cell with the same number of chromosomes as the somatic cells of the organism divides twice, producing four haploid daughter cells. Each cell has half the number of chromosomes of the original parent cell.

## Stages of Meiosis:

**Meiosis I - division of homologous chromosomes**

1. **Interphase:** As in mitosis, DNA replication occurs during interphase.
2. **Prophase I:** chromosomes start to shorten and thicken; nuclear membrane starts to dissolve; centrioles start to move to opposite poles and spindle fibres start to form.

Figure 6.2 During crossing over, sister chromatids of homologous chromosomes exchange segments. This results in recombinant chromosomes containing chromosomes containing segments from both of the original chromosomes.

- Chromosomes come together in homologous pairs. Each chromosome of the pair is composed of a pair of sister chromatids. The whole structure is then referred to as a tetrad because each pair of chromosomes is composed of four chromatids. Each sister chromatid is intertwined with a sister chromatid from its matching homologous chromosome, a process called **synapsis**.
- **Crossing Over** occurs during prophase I, whereby intertwined chromatids from different chromosomes break and reattach to each other - exchanging sections of genetic material. This results in increased variation as a result of the recombination of genetic information.

3. **Anaphase I:** the tetrads (made up of pairs of homologous chromosomes) align their centromeres across the middle of the cell.
