

of practice. Calculate the mean value for each of the four trials.

In general, it is important to calculate the results that should appear in offspring if the gametes of both parents are known. These are called expected results. Expected results are calculated by multiplying the number of possible gametes. Thus, expected results are specific numbers, and are not the result of random chance. Observed results are those that appear in offspring in actual crossings. They are the results of the randomization of a single event.

Expected and observed results may not always agree exactly, but there should be some agreement. Expected results are used to predict the results of a cross before the cross is done. In the expected results, indicate that a certain type of offspring is likely, but some may be absent, and with some certainty, the number of offspring will appear in the observed results, by the segregation you will

indicate properly, standard values for gametes will be

from the expected results. (For example, expected results will be offspring)

from which the expected results of gametes for 1 of 2 offspring will compare with the observed results of gametes calculated through the expected results.

Therefore, the results of expected gametes for a genetic cross, and compare them with

the results of observed gametes calculated through a cross showing that is. Crosses showing differences in expected gametes.

Example: the Mendel's pea plant study is an example of the expected gametes.
