

1. 1-What is an algorithm? What are the five important features of an algorithm?

ANS-An algorithm is a precise, step-by-step set of instructions or a well-defined procedure that outlines how to solve a particular problem or perform a specific task. Algorithms are fundamental to computer science and mathematics and are used to solve a wide range of problems, from sorting data to searching for information on the internet.

The five important features of an algorithm are:

1. **Finiteness:** An algorithm must have a finite number of steps, meaning it will eventually terminate after a finite number of instructions. It should not go into an infinite loop.
2. **Definiteness:** Each step of the algorithm must be well-defined and unambiguous, leaving no room for interpretation. Anyone following the algorithm should know precisely what to do at each step.
3. **Input:** An algorithm takes zero or more inputs, which are the data or values it operates on to produce a result. These inputs are typically specified before the algorithm begins execution.
4. **Output:** An algorithm produces at least one output, which is the result of applying the algorithm to the given inputs. The output should relate to the problem or task the algorithm is designed to solve.
5. **Effectiveness:** An algorithm must be effective, meaning that it can be executed using a finite amount of resources (time and memory). It should be feasible to implement the algorithm using the available computational resources.

-
2. 2-List any five design approaches for developing fast and efficient algorithms.

ANS-Developing fast and efficient algorithms is a crucial aspect of computer science and software development. Various design approaches can help achieve this goal. Here are five design approaches for developing fast and efficient algorithms:

1. **Divide and Conquer:** This approach involves breaking down a complex problem into smaller, more manageable subproblems. Each subproblem is solved independently, and then their solutions are combined to solve the original problem. Examples of algorithms that use this approach include merge sort and quicksort for sorting data.
2. **Dynamic Programming:** Dynamic programming is a technique for solving problems by breaking them down into overlapping subproblems and caching
