Dead Spot

Dead spot, also known as bentgrass dead spot and bermuda-grass dead spot, is a disease of young stands of *Agrostis* and hybrid *Cynodon* turf grown in soil mixes with a high sand content on golf greens and tees in the United States. The pathogen has been observed in the spring on *Poa trivialis* that was overseeded into *Cynodon* greens. Dead spot may develop on older greens that were planted after fumigation of the soil with methyl bromide. The disease is not known to affect turfs grown in native soils.

Symptoms

In close-mown *Agrostis* on golf greens and tees, dead spot initially appears as small reddish brown spots (Figs. 225 and 226), approximately 0.5 in. (1 cm) in diameter, which enlarge to about 3.5 in. (8 cm) in diameter. In the early stages of disease development, the spots are reddish brown or copper-colored and look like ball-mark injury. As the disease progresses, grass in the center of a spot turns tan, while leaves in the outer edge of the spot appear reddish brown (Fig. 227). Rings of dead grass with living turf in the center (frog-eyes) may occur but are uncommon. Roots and stem bases of dying plants are discolored or necrotic. Patches may be distributed throughout a green or may be localized. The spots generally do not coalesce, except in severe cases. They sometimes form depressions or pits in the putting surface. The spots recover very slowly; stolon growth into dead patches appears restrained or inhibited. Foliar mycelium is not observed in the field, but a white to pale pink mycelium may develop on leaves of diseased plants incubated under high humidity for three to five days. Numerous
