

## Calculating Local Water Budgets

A local water budget is a mathematical model of the water cycle for a region. It illustrates how the income, outgo, and storage of water vary over the course of an average year. The local water budget may show periods of water deficit when the total supply is less than the total demand, and it may show surplus when there is more water available than can be used or stored.

The water budget is a model that is used to analyze the changes that occur within an area. The model is an approximation for a general area and does not always represent specific conditions at all locations within the region.

Abbreviations used in the water budget tables:

P = Precipitation

$E_p$  = Potential Evapotranspiration

$P - E_p$  = The difference between precipitation and potential evapotranspiration

$\Delta St$  = Change in soil storage

St = Soil storage

$E_a$  = Actual Evapotranspiration

D = Deficit

S = Surplus

Compute the water budgets for Syracuse, New York; Alexandria, Louisiana; and El Paso, Texas using the information in the tables provided. After calculating the water budgets, plot a graph for each city on the grid provided.

- ☐ Only data for P,  $E_p$ , and  $E_a$  are to be plotted.
- ☐ Use a line of different color for each factor.
- ☐ The areas between the plotted lines show surpluses, deficits, usage, and recharge. Label these areas, and shade them as shown by the key. Note that the size of the area between the lines is a measure of the amount of surplus, deficit, usage, or recharge.
