## Optimal experimental design

Customize the experiment for the setting instead of adjusting the setting to fit a classical design.

Byran Smucker, Martin Krzywinski and Naomi Altman

To maximize the chance for success in an experiment, good experimental design is needed. However, the presence of unique constraints may prevent mapping the experimental scenario onto a classical design. In these cases, we can use optimal design: a powerful, general-purpose tool that offers an attractive alternative to classical design and provides a framework within which to obtain high-quality, statistically grounded designs under nonstandard conditions. It can flexibly accommodate constraints, is connected to statistical quantities of interest and often mimics intuitive classical designs.

For example, suppose we wish to test the effects of a drug's concentration in the range 0–100 ng/ml on the growth of cells. The cells will be grown with the drug in test tubes, arranged on a rack with four shelves. Our goal may be to determine whether the drug has an effect and precisely estimate the effect size or to identify the concentration at which the response is optimal. We will address both by finding designs that are optimal for regression parameter estimation as well as designs optimal for prediction precision.

To illustrate how constraints may influence our design, suppose that the shelves receive different amounts of light, which might lead to systematic variation between shelves. The shelf would therefore be a natural 'block'. Since we don't expect such systematic variation within a shelf, the order of tubes on a shelf can be randomized. Furthermore, each shelf can only hold nine test tubes. The experimental design question, then, is: What should be the drug concentration in each of the 36 tubes?

If concentration were a categorical factor, we could compare the mean response at nine concentrations—a traditional randomized complete block design (RCBD)<sup>1</sup>. However, because concentration is actually continuous, discrete levels unduly limit which concentrations are studied and reduce our ability to detect an effect and estimate the concentration that produces an optimal response. Classical designs, like full factorials or RCBDs, assume an ideal and simple experimental setup, which may be inappropriate for all experimental goals or untenable in the presence of constraints.

Optimal design provides a principled approach to accommodating the entire range of concentrations and making full use of each shelf's capacity. It can incorporate a variety of constraints such as sample size restrictions (e.g., the lab has a limited supply of test tubes), awkward blocking structures (e.g., shelves have different capacities) or disallowed treatment combinations (e.g., certain combinations of factor levels may be infeasible or otherwise undesirable).

To assist in describing optimal design, let's review some terminology. The drug is a 'factor', and particular concentrations are 'levels'. A particular combination of factor levels is a 'treatment' (with just a single factor, a treatment is simply a factor level) applied to an 'experimental unit', which is a test tube. The shelves are 'blocks', which are collections of experimental units that are similar in traits (e.g., light level) that might affect the experimental outcome<sup>2</sup>. The possible set of treatments that could be chosen is the 'design space'. A 'run' is the execution of a single experimental unit, and the 'sample size' is the number of runs in the experiment.

Optimal design optimizes a numerical criterion, which typically relates to the variance or other statistically relevant properties of the design, and uses as input the number of runs, the factors and their possible levels, block structure (if any), and a hypothesized form of the relationship between the response and the factors. Two of the most common criteria are the D-criterion and the I-criterion. They are fundamentally different: the D-criterion relates to the variance of factor effects, and the I-criterion addresses the precision of predictions.

To understand the D-criterion (determinant), suppose we have a quadratic regression model<sup>3</sup> with parameters  $\beta_0$  and  $\beta_1$  that relate the factor to the response (for simplicity, ignore  $\beta_0$ , the intercept). Our estimates of these parameters,  $\hat{\beta}_0$  and  $\hat{\beta}_1$ , will have error and, assuming the model error variance is known, the D-optimal design minimizes the area of the ellipse that defines the joint confidence interval for the parameters (Fig. 1). This area will include the true values of both  $\beta_0$  and  $\beta_1$  in 95% (or some other desired proportion) of repeated

**Fig. 1 |** The confidence ellipse of a regression model with two parameters,  $\beta_0$  and  $\beta_1$ . The ellipse can be projected onto each axis to obtain the familiar one-dimensional confidence intervals for each parameter (shown as blue points, with error bars). The D-criterion reduces the variance of the parameter estimates and/or the correlation between the estimates by minimizing the area of the ellipse.

executions of the design, and its size and shape are a function of the data's overall variance and the design.

On the other hand, the I-criterion (integrated variance) is used when the experimental goal is to make precise predictions of the response, rather than to obtain precise estimates of the model parameters. An I-optimal design chooses the set of runs to minimize the average variance in prediction across the joint range of the factors. The prediction variance is a function of several elements: the data's overall error variance, the factor levels at which we are predicting, and also the design itself. This criterion is more complicated mathematically because it involves integration.

For both criteria, numerical heuristics are used in the optimization but they do not guarantee a global optimum. For most scenarios, however, near-optimal designs are adequate and not hard to obtain.

Returning to our example, suppose we wish to obtain a precise estimate of our drug's effect on the mean response. If we expect that the effect is linear (our model has one parameter of interest,  $\beta_1$ , which is the slope), the D-optimal design places either four or five experimental units in each block at the low level (0 ng/ml) and the

Polycarpou, Christos Panayiotou, Georgios Ellinas, 2009-09-16 This volume is part of the two volume proceedings of the 19th International Conference on Artificial Neural Networks ICANN 2009 which was held in Cyprus during September 14-17, 2009. The ICANN conference is an annual meeting sponsored by the European Neural Network Society (ENNS) in cooperation with the International Neural Network Society (INNS) and the Japanese Neural Network Society (JNNS). ICANN 2009 was technically sponsored by the IEEE Computational Intelligence Society. This series of conferences has been held annually since 1991 in various European countries and covers the field of neurocomputing, learning systems and related areas. Artificial neural networks provide an information processing structure inspired by biological nervous systems. They consist of a large number of highly interconnected processing elements with the capability of learning by example. The field of artificial neural networks has evolved significantly in the last two decades with active participation from diverse fields such as engineering, computer science, mathematics, artificial intelligence, system theory, biology, operations research and neuroscience. *Applications of Linear and Nonlinear Models* Erik Grafarend, Joseph L. Awange, 2012-08-15 Here we present a nearly complete treatment of the Grand Universe of linear and weakly nonlinear regression models within the first 8 chapters. Our point of view is both an algebraic view as well as a stochastic one. For example, there is an equivalent lemma between a best linear unbiased estimation (BLUE) in a Gauss-Markov model and a least squares solution (LS) in a system of linear equations. While BLUE is a stochastic regression model, LS is an algebraic solution. In the first six chapters, we concentrate on underdetermined and overdetermined linear systems as well as systems with a datum defect. We review estimators, algebraic solutions of type MINOLESS, BLIMBE, BLUMBE, BLUE, BIQUE, BLE, BIQUE and Total Least Squares. The highlight is the simultaneous determination of the first moment and the second central moment of a probability distribution in an inhomogeneous multilinear estimation by the so-called E-D correspondence as well as its Bayes design. In addition, we discuss continuous networks versus discrete networks, use of Grassmann-Plücker coordinates, criterion matrices of type Taylor-Karman as well as FUZZY sets. Chapter seven is a speciality in the treatment of an overdetermined system of nonlinear equations on curved manifolds. The von Mises-Fisher distribution is characteristic for circular or hyperspherical data. Our last chapter, eight, is devoted to probabilistic regression, the special Gauss-Markov model with random effects leading to estimators of type BLIP and VIP including Bayesian estimation. A great part of the work is presented in four Appendices. Appendix A is a treatment of tensor algebra, namely linear algebra, matrix algebra and multilinear algebra. Appendix B is devoted to sampling distributions and their use in terms of confidence intervals and confidence regions. Appendix C reviews the elementary notions of statistics, namely random events and stochastic processes. Appendix D introduces the basics of

Groebner basis algebra its careful definition the Buchberger Algorithm especially the C F Gauss combinatorial algorithm

Melas, 2006-04-20 The present book is devoted to studying optimal experimental designs for a wide class of linear and nonlinear regression models. This class includes polynomial, trigonometrical, rational, and exponential models, as well as many particular models used in ecology and microbiology. As the criteria of optimality, the well-known D, E, and c criteria are implemented. The main idea of the book is to study the dependence of optimal signs on values of unknown parameters and on the bounds of the design interval. Such a study can be performed on the basis of the Implicit Function Theorem, the classical result of functional analysis. The idea was first introduced in the author's paper Melas 1978 for nonlinear in parameters exponential models. Recently it was developed for other models in a number of works Melas 1995, 2000, 2001, 2004, 2005. Dette Melas 2002, 2003. Dette Melas, Pepelyshev 2002, 2003, 2004b, and Dette Melas, Biederman 2002.

The purpose of the present book is to bring together the results obtained and to develop further underlying concepts and tools. The approach mentioned above will be called the functional approach. Its brief description can be found in the Introduction. The book contains eight chapters. The first chapter introduces basic concepts and results of optimal design theory initiated mainly by J. Kiefer. **Optimum Designs for Multi-Factor Models** Rainer Schwabe, 2012-12-06 In real applications, most

experimental situations are influenced by a large number of different factors. In these settings, the design of an experiment leads to challenging optimization problems, even if the underlying relationship can be described by a linear model. Based on recent research, this book introduces the theory of optimum designs for complex models and develops general methods of reduction to marginal problems for large classes of models with relevant interaction structures. **Semidistributive**

**Modules and Rings** A.A. Tuganbaev, 2012-12-06 A module  $M$  is called distributive if the lattice  $\text{Lat } M$  of all its submodules is distributive, i.e.  $F \cap (G + H) = (F \cap G) + (F \cap H)$  for all submodules  $F, G$  and  $H$  of the module  $M$ . A module  $M$  is called uniserial if all its submodules are comparable with respect to inclusion, i.e. the lattice  $\text{Lat } M$  is a chain. Any direct sum of distributive resp. uniserial modules is called a semidistributive resp. serial module. The class of distributive resp. semidistributive modules properly contains the class of all uniserial resp. serial modules. In particular, all simple resp. semisimple modules are distributive resp. semidistributive. All strongly regular rings, for example, all factor rings of direct products of division rings and all commutative regular rings, are distributive. All valuation rings, division rings, and all commutative Dedekind rings are g.

rings of integral algebraic numbers or commutative principal ideal rings are distributive A module is called a Bezout module or a locally cyclic module if every finitely generated submodule is cyclic If all maximal right ideals of a ring A are ideals e g if A is commutative then all Bezout A modules are distributive      Applications of Lie Algebras to Hyperbolic and Stochastic Differential Equations Constantin Vârsan, 2012-12-06 The main part of the book is based on a one semester graduate course for students in mathematics I have attempted to develop the theory of hyperbolic systems of differential equations in a systematic way making as much use as possible of gradient systems and their algebraic representation However despite the strong similarities between the development of ideas here and that found in a Lie algebras course this is not a book on Lie algebras The order of presentation has been determined mainly by taking into account that algebraic representation and homomorphism correspondence with a full rank Lie algebra are the basic tools which require a detailed presentation I am aware that the inclusion of the material on algebraic and homomorphism correspondence with a full rank Lie algebra is not standard in courses on the application of Lie algebras to hyperbolic equations I think it should be Moreover the Lie algebraic structure plays an important role in integral representation for solutions of nonlinear control systems and stochastic differential equations yielding results that look quite different in their original setting Finite dimensional nonlinear filters for stochastic differential equations and say decomposability of a nonlinear control system receive a common understanding in this framework      Recent Advances in Statistics and Probability J.
