PASCAL. ,1994 Gramática descriptiva de la lengua española: Entre la oración y el discurso. Morfología
Violeta Demonte,1999 *The TRANSMED Atlas. The Mediterranean Region from Crust to Mantle* William Cavazza,Francois M. Roure,Wim Spakman,Gerard M. Stampfli,Peter A. Ziegler,2012-12-06 A publication of the Mediterranean Consortium for the 32nd International Geological Congress

Estructuras tectónicas recientes en la transversal central de las Cordilleras Béticas Patricia Ruano Roca,2003 Las estructuras tectónicas activas en las Cordilleras Béticas acomodan la convergencia oblicua con orientación NO SE entre las placas Euroasiática y Africana La transversal central de las Cordilleras Béticas permite entender las relaciones entre las estructuras que deforman las Zonas Internas y las Zonas Externas A pesar del carácter convergente del límite de placas la mayor parte de fallas presentes en esta transversal son normales y muestran un contexto extensional Sin embargo la mayor parte de la región muestra un período levantamiento desde el Mioceno que sería más temprano de una región en compresión Los datos geofísicos permiten determinar los principales rasgos de la estructura profunda de la región Mientras que en el mar de Alborán los datos de sismica de refracción indican la presencia de una corteza continental delgada 15 Km hacia las Cordilleras Béticas se produce un período engrosamiento de la corteza de hasta 36-37 km Los estudios gravimétricos indican que el engrosamiento cortical es brusco y se produce en una posición próxima a la línea de costa Los perfiles de sismica de reflexión profunda en las cordilleras muestran reflectores horizontales en la corteza inferior que no están afectados por los grandes pliegues de la corteza superior La continuidad de anomalías aeromagnéticas del Macizo Ibérico bajo las zonas externas de las Cordilleras Béticas hacia que dichos materiales constituyen el basamento de estas últimas Todos estos datos sugieren que las rocas que forman las Cordilleras Béticas están despegadas sobre un zócalo que estaría constituido por el Macizo Ibérico Este despegue constituiría la principal estructura activa de las Cordilleras Béticas con un movimiento relativo del bloque de techo hacia el NO Las estructuras observadas en campo a lo largo de la transversal indican que a partir del Mioceno superior se han desarrollado tanto pliegues como fallas que determinan el relieve actual en la transversal Desde la línea de costa hacia el N la Sierra Tejeda constituye una gran antiforma de dirección media E-O Esta antiforma tardía deforma una superposición de varias unidades alpujarrides separadas por fallas normales de bajo ángulo de edad Mioceno inferior Los buzamientos de los materiales alpujarrides presentan en la línea de costa generalmente buzamientos hacia el S del mismo modo que ocurre en depósitos costeros pliocuaternarios El sistema de fallas normales con buzamientos hacia el SO que son activas en otros sectores de la Cordillera como en Sierra Nevada occidental no controlan la morfología costera y en algunos puntos aparecen fosilizadas por materiales pliocuaternarios Por ello la línea de costa podría estar determinada por el desarrollo del pliegue de gran radio El flanco norte del Pliegue de Sierra Tejeda se prolonga bajo la Depresión de Granada Esta depresión tiene una estructura de cuña que se abre hacia el N de determinada por una falla normal en su borde norte Esta falla ha sido activa al menos desde el Tortoniense

hasta la actualidad ya que condiciona el depósito de materiales de estas edades tal y como indican los datos geofísicos y geología de campo. Hacia el Norte los pliegues post-tortonienses determinan la geometría del relieve. Cabe destacar la Depresión de Alcalá la Real en la que afloran materiales desde el Mioceno superior y cuya geometría está determinada por pliegues de actividad progresiva de dirección NO-SE y NE-SO. En el frente de las cordilleras que constituye el límite entre las Cordilleras y la Depresión del Guadalquivir se observan fallas inversas con dirección E-O a ENE-OSO que afectan al menos a materiales tortoniense aunque no se ha observado la relación con materiales más recientes. También se han observado fallas E-O e salto en dirección sinistra. El estudio de dos sectores en Marruecos uno en el frente de las Cordilleras Rifea y otro en la Meseta permiten comparar la distribución de las deformaciones en ambos frentes de las Cordilleras Béticas Rifeas. Donde se observa un frente activo con pliegues cabalgamientos y fallas ciegas que indican movimientos del bloqueo de techo hacia el Sur. Las determinaciones de paleoesfuerzos se han realizado a partir de microfallas maclado de calcita y sobre todo del análisis de cantos estriados de conglomerados del Plioceno y el Cuaternario. En cada canto se ha considerado tanto las marcas de disolución con las estriaciones en su superficie. Las determinaciones de paleoesfuerzos indican que el estado de esfuerzos ha tenido un carácter muy variable en la región para el mismo periodo de tiempo. Sierra Tejeda y la parte Sur de la Depresión de Granada han sufrido una extensión radial desde el Mioceno superior aunque direcciones de extensión NE-SO bien definidas han sido determinadas. Sin embargo en el borde norte de la Depresión de Granada se han identificado compresiones subhorizontales con elipsoide proláticos perpendiculares de dirección NO-SE y NE-SO. Hacia el frente de las Cordilleras Béticas los paleoesfuerzos permiten reconocer tres eventos: dos comprensivos con elipsoides de esfuerzo proláticos NO-SE y NE-SO y uno extensivo NO-SE. Las observaciones y datos anteriores muestran que las principales estructuras asociadas al acortamiento de las Cordilleras Béticas desde el Mioceno superior con los pliegues de tamaño kilométrico y de direcciones variables entre los que predominan los de E-O a NE-SO en las cordilleras Béticas y fallas inversas en las Cordilleras Rifeas. Los despegues corticales en ambas cordilleras. Los pliegues se habrán desarrollado a techo de un gran despegue basal que separa a las rocas de la Cordillera Bética del basamento formado por las rocas del Macizo Ibérico. El desarrollo de estas estructuras sería el responsable del engrosamiento cortical y la elevación de la cordillera desde el Tortoniense. La elevación topográfica favorecería la presencia de fallas normales en la parte superior de la corteza que no se prolongan en las zonas media y profunda de la corteza. No obstante las fallas inversas se localizan preferentemente en el frente de las cordilleras. El hecho de que el salto de estas fallas sea relativamente pequeño indica que la mayor parte del acortamiento estuvo acomodado en los grandes pliegues que se desarrollan en superficie. Los paleoesfuerzos también confirman el predominio de la extensión en la zona más interna de las cordilleras y la compresión en las zonas más externas de las mismas. No obstante el campo de esfuerzo ha debido de ser complejo puesto que se han detectado direcciones de compresión perpendiculares en zonas muy próximas. Todo esto indica que la deformación desde el Mioceno superior ha sido más o menos continua aunque con diferentes

caracter sticas en cada regi n de las Cordilleras B ticas lo que impide la diferenciaci n de fases de deformaci n regionales que afecten por igual a todas las cordilleras *Libros en venta en Hispanoamérica y España*, 1993 **Libros de Mexico**, 1987
