Advances in Portable X-ray Fluorescence Spectrometry B Lee Drake, Brandi L MacDonald, 2022-10-19 Over the last two decades advances in the design miniaturization and analytical capabilities of portable X ray fluorescence pXRF instrumentation have led to its rapid and widespread adoption in a remarkably diverse range of applications in research and industrial fields The impetus for this volume was that as pXRF continues to grow into mainstream use analysts should be increasingly empowered with the right information to safely and effectively employ pXRF as part of their analytical toolkit This volume provides introductory and advanced level users alike with readings on topics ranging from basic principles of pXRF and qualitative and quantitative approaches through to machine learning and artificial intelligence for enhanced applications It also includes fundamental guidance on calibrations the mathematics of calculating uncertainties and an extensive reference index of all elements and their interactions with X rays Contributing authors have provided a wealth of information and case studies in industry specific chapters These sections delve into detail on current standard practices in industry and research including examples from agricultural and geo exploration sectors research in art and archaeology and metals industrial and regulatory applications As pXRF continues to grow in use in industrial and academic settings it is essential that practitioners continue to learn share and implement informed and effective use of this technique This volume serves as an accessible guidebook and go to reference manual for new and experienced users in pXRF to achieve this goal

The Late Eocene Earth Christian Koeberl, Alessandro Montanari, 2009 The Late Eocene and the Eocene Oligocene E O transition mark the most profound oceanographic and climatic changes of the past 50 million years of Earth history with cooling beginning in the middle Eocene and culminating in the major earliest Oligocene Oi 1 isotopic event The Late Eocene is characterized by an accelerated global cooling with a sharp temperature drop near the E O boundary and significant stepwise floral and faunal turnovers These global climate changes are commonly attributed to the expansion of the Antarctic ice cap following its gradual isolation from other continental masses However multiple extraterrestrial bolide impacts possibly related to a comet shower that lasted more than 2 million years may have played an important role in deteriorating the global climate at that time This book provides an up to date review of what happened on Earth at the end of the Eocene Epoch

Chemostratigraphy: Concepts, Techniques, and Applications , Geochemistry and High-resolution Chemostratigraphy of the Haynesville Formation, East Texas Rita Bitar Nehme, 2015 The Upper Jurassic Haynesville Formation of East Texas and Louisiana is an organic rich calcareous mudrock that is Kimmeridgian in age It underlies the less calcareous Bossier Shale and it overlies the Smackover Formation limestone The Haynesville has low permeability but a relative high porosity compared to other mudrock formations Mudrocks are the most common sedimentary rock and some of the most challenging to study analyze and understand Despite having a homogeneous appearance on a macroscopic scale mudrocks often have high variability in facies and composition on the microscopic scale and elemental level Many studies and methods have been developed to identify facies and stratigraphic variations in mudrocks A complete understanding of these variations is valuable to comprehend paleoenvironments paleoclimate and paleoceanographic conditions Mudrocks studies are also beneficial to shale exploration because these formations which have a high hydrocarbon content can be targeted by oil and gas companies for exploration and production Geochemical methods chemostratigraphy in particular will be used in this thesis to complement core description petrophysical studies and sedimentological studies This thesis focuses on acquiring chemostratigraphic data from X Ray Fluorescence XRF and X Ray Diffraction XRD measurements to identify elemental and mineralogical variations in the T W George core from the Haynesville Formation in Harrison County Texas The data are linked to core description and are analyzed using Hierarchical Cluster Analysis HCA to acquire a better understanding of the paleoceanographic conditions and depositional environments that controlled the sediment deposition of

the Haynesville Formation The Haynesville Formation comprises a Ca rich lower Haynesville a more Ca rich upper Haynesville and underlies the Si rich and Ca poor Bossier The dominant condition during deposition is anoxic euxinic in the lower Haynesville becoming dysoxic in the upper Haynesville and more oxygenated in the Bossier Formation The greenhouse climate of the Late Jurassic led to the deposition of strata yielding petroleum source rocks such as the Haynesville Formation that today have great economic value Thus studying the Haynesville has both academic and economic importance

Chemostratigraphy, Paleoceanography, and Sequence Stratigraphy of the Pennsylvanian-Permian Section in the Midland Basin of West Texas, with Focus on the Wolfcamp Formation Milton Cortez, 2012 The late Pennsylvanian to early Permian rocks Wolfcampian and Leonardian of the Midland Basin represent a single lithologic unit composed primarily of calcareous mudrocks siliceous mudrocks muddy carbonate clast conglomerates and skeletal packstones grainstones at the approximate depositional center located in Reagan County Texas Pure versions of these lithologic end members are discretely distributed among a multitude of transitional lithofacies The Midland Basin evolved in the foreland of the Ouachita Fold belt from Mississippian to early Permian time along side several sub basins of the Permian Basin These basins were formed by dissection and uplift associated with the continental collision of Laurasia and Gondwana to form Pangea in the Late Paleozoic Wolfcampian and Leonardian clastics were deposited into the basin as a result of a rapid increase in accommodation due to basin subsidence and proximal uplift of the Central Basin Platform in concurrence with glacially driven eustatic sea level fluctuations influenced by the Late Paleozoic Ice Age LPIA Various aspects of Penn Perm strata that were studied include degree of basin restriction redox conditions sediment input paleoceanography bulk geochemistry and sequence stratigraphy Four drill cores located in Reagan and Martin Counties were scanned at a 1 foot interval with a hand held energy dispersive x ray fluorescence HH ED XRF spectrometer to provide quantitative analysis of major e g Fe Si Al and trace e g Mo Cr V elements In addition total organic carbon TOC total inorganic carbon TIC X Ray Diffraction XRD spectroscopy and stable isotopes of organic carbon $\delta^{13}\text{C}_{\text{org}}$ were analyzed in two of the cores Focus of the project was to thoroughly define the chemostratigraphy of a continuous core through the Leonardian and Wolfcampian strata in Reagan County Secondly study of intermittent core through the Spraberry Dean Strawn and Atoka Formations in the Martin County core provided insight into the overall evolution of the Midland Basin from Atokan to the Guadalupian time The area of study is located off of the shelf slope into marginal basin settings and is oriented parallel to the Eastern Shelf between the Ozona Arch and the Eastern Shelf Nose The physical paleoceanography of the Penn Perm section reveals an overall high degree of basin restriction at the time of deposition while large scale study revealed an overarching trend of basin deepening along side an increase in primary production seen in several scales of cyclic stair stepping negative $\delta^{13}\text{C}_{\text{org}}$ excursions Fluctuations in the degree of restriction and water mass mixing were studied through the chemical paleoceanographic interpretation of several distinct zones enriched in redox sensitive trace metals Mo V Ni and Zn and or

detrital sediments Ca Fe Si Mg and K normalized to clay Individual zones labeled Detrital DZ Detrital Anoxic DAZ and Anoxic AZ were linked to changes in basin dynamics and ultimately associated with a complete LPIA driven lowstand to highstand sequence stratigraphic cycle Ultimately a thorough chemostratigraphy was developed on Late Pennsylvanian through Permian age mudrocks Correlations between chemostratigraphy paleoceanography and sequence stratigraphy have enhanced the ability to assess the economic potential of Midland Basin Penn Perm rocks as an unconventional source reservoir Furthermore the study has laid the groundwork for future attempts to make similar correlations between mudrock geochemistry to marine basin dynamics

Chemostratigraphy of the Mississippian-age Barnett Formation, Fort Worth Basin, Wise County, Texas USA Chizoba Charity Nsianya, ProQuest Dissertations and Theses (Electronic resource collection), University of Texas at Arlington. College of Science, 2013 The Mississippian age Barnett Formation is a shale gas system dominated by fine grained clay to silt size particles deposited in the Fort Worth Basin a peripheral foreland basin that formed during the late Paleozoic as a result of continental collision between Laurasia and Gondwana A detailed assessment of the chemostratigraphy and depositional environment of the Barnett Formation in the northern end of Fort Worth Basin Texas will be studied using a variety of geochemical methods One drill core located in the south eastern part of Wise County Texas USA was scanned at high resolution 2 inch interval using a hand held X ray fluorescence ED XRF spectrometer in order to provide a quantitative analysis of its major e g Si Ca Al and trace e g MO U V element geochemistry Furthermore total organic carbon TOC total inorganic carbon TIC and total nitrogen TN data were collected at one foot sample spacing Major element geochemistry Si Al suggests a silica rich mudstone however relative proportions of % silica SiO₂ and Zircon Zr suggest that most of this excess silica in the Barnett Formation is biogenic in origin Trace element relationships reveal that the Barnett Formation in the northern Fort Worth Basin was deposited under anoxic euxinic conditions with relatively high total organic carbon concentration ranging from 2.0 to approximately 8 % The organic matter provenance was determined to be primarily of marine origin Changes in the stratigraphy using EFe Al together with DOPT also confirm that the Barnett Formation lower interval contains abundant iron relative to normal gray shale

Chemostratigraphy and Paleoenvironment of the Smithwick Formation, Fort Worth Basin, San Saba County, Texas Elisha Nichole Hughes, 2011 The Early Pennsylvanian Age Smithwick Formation was deposited in the tectonically active Fort Worth Basin in North Central Texas during a time of well documented global climatic instability during the Late Paleozoic ice age Geochemical and stable isotopic results from two cores recovered from the southwestern portion of the FWB provide paleoenvironmental insight into the conditions under which the Smithwick was deposited Specifically major element geochemistry and mineralogical results suggest a depositional setting grading from a carbonate rich facies Marble Falls and Big Saline into a transgressive siliciclastic dominated mudrock Smithwick that coarsens upward into a progradational mudrock and silt sand sequence Atoka and Strawn While robust geochronological constraints are lacking for Middle

Carboniferous strata subtle oscillations in the detrital geochemical proxies Si Al Ti Al may provide a temporal framework assuming they are a result of orbital forcing Furthermore thin siderite rich intervals may indicate discrete periods of amplified eolian deposition due to the aridification associated with glaciation on Gondwana Alternatively the siderites may reflect a more localized signature of changes in a tropical paleoclimate Integration of trace metal Fe S TOC relationships and the overall lack of preserved fauna suggest largely suboxic bottom water conditions in the basin Average TOC for the Smithwick is 1.5% and the organic matter is dominantly marine algal based on C/N molar ratios of 6.6 to 17.5 and $\delta^{13}\text{C}$ values of 23.1 to 25.7 ‰ Integration and interpretation of the results suggest that the Smithwick represents a marginally productive environment that existed during the early stages of subsidence of the Fort Worth Basin
